

# Initial value problem of a finite beta asymmetric magnetic slab

## 1 Basic equations

From [1],

$$\frac{1}{\rho(\omega^2 - \omega_A^2)} \left( \frac{\partial^2}{\partial x^2} - m^2 \right) \hat{p}_T = f(\omega, x), \quad (1)$$

where

$$f(\omega, x) = \frac{\partial}{\partial x} \frac{\dot{\xi}_{x0} - i\omega\xi_{x0}}{\rho(\omega^2 - \omega_A^2)} + ik_y \frac{\dot{\xi}_{y0} - i\omega\xi_{y0}}{\rho(\omega^2 - \omega_A^2)} + ik_z \frac{c_0^2}{c_0^2 + v_A^2} \frac{\dot{\xi}_{z0} - i\omega\xi_{z0}}{\rho(\omega^2 - \omega_T^2)}, \quad (2)$$

$$m^2 = m(\omega)^2 = \frac{(\omega_1^2 - \omega^2)(\omega_2^2 - \omega^2)}{(c_0^2 + v_A^2)(\omega_T^2 - \omega^2)}, \quad (3)$$

$$\omega_1^2 = \frac{1}{2}(k_y^2 + k_z^2)(c_0^2 + v_A^2) \left( 1 - \sqrt{1 - \frac{4\omega_T^2}{(k_y^2 + k_z^2)(c_0^2 + v_A^2)}} \right), \quad (4)$$

$$\omega_2^2 = \frac{1}{2}(k_y^2 + k_z^2)(c_0^2 + v_A^2) \left( 1 + \sqrt{1 - \frac{4\omega_T^2}{(k_y^2 + k_z^2)(c_0^2 + v_A^2)}} \right). \quad (5)$$

Take  $k_y \ll k_z$  and  $\xi_{y0} = \dot{\xi}_{y0} = 0$ , then

$$\left( \frac{\partial^2}{\partial x^2} - m^2 \right) \hat{p}_T = f(\omega, x), \quad (6)$$

where

$$f(\omega, x) = \frac{\partial}{\partial x} (\dot{\xi}_{x0} - i\omega\xi_{x0}) + ik_z \frac{c_0^2}{c_0^2 + v_A^2} \frac{(\omega^2 - \omega_A^2)}{(\omega^2 - \omega_T^2)} (\dot{\xi}_{z0} - i\omega\xi_{z0}), \quad (7)$$

$$m^2 = \frac{(\omega_0^2 - \omega^2)(\omega_A^2 - \omega^2)}{(c_0^2 + v_A^2)(\omega_T^2 - \omega^2)}, \quad (8)$$

where we have defined the initial values by

$$\xi_x(x, 0) = \xi_{x0}, \quad \frac{\partial \xi_x}{\partial t}(x, 0) = \dot{\xi}_{x0}, \quad \xi_z(x, 0) = \xi_{z0}, \quad \frac{\partial \xi_z}{\partial t}(x, 0) = \dot{\xi}_{z0}. \quad (9)$$

Considering a magnetic slab in a non-magnetic environment, we have

$$m_0^2 = -\frac{(\omega^2 - \omega_0^2)(\omega^2 - \omega_A^2)}{(c_0^2 + v_A^2)(\omega^2 - \omega_T^2)}, \quad m_{1,2}^2 = \frac{\omega_{1,2}^2 - \omega^2}{c_{1,2}^2}, \quad (10)$$

$$f_{1,2}(\omega, x) = \frac{\partial}{\partial x}(\dot{\xi}_{x0} - i\omega \xi_{x0}) + ik(\dot{\xi}_{z0} - i\omega \xi_{z0}). \quad (11)$$

## 2 Solution in Laplace space

### 2.1 Solution within the slab

For the solution inside the slab,  $|x| < x_0$ ,  $\hat{p}_T(x)$  satisfies

$$\left( \frac{\partial^2}{\partial x^2} - m_0^2 \right) \hat{p}_T = f_0(\omega, x), \quad (12)$$

under the boundary conditions  $\hat{p}_T(-x_0) = \hat{A}_1$  and  $\hat{p}_T(x_0) = \hat{A}_2$ . To solve this we construct the Green's function,  $G_0(x; s)$  that satisfies

$$\frac{d^2 G_0}{dx^2} - m_0^2 G_0 = \delta(x - s), \quad G_0(-x_0; s) = G_0(x_0; s) = 0, \quad (13)$$

where  $\delta$  denotes the Dirac delta function. The general solution of this equation is

$$G_0(x; s) = c_1 \sinh(m_0(x - x_0)) + c_2 \sinh(m_0(x + x_0)), \quad (14)$$

where  $c_1 = 0$  for  $x < s$  and  $c_2 = 0$  for  $x > s$ . Ensuring  $G_0$  and  $\partial G_0 / \partial x$  have jumps of 0 and 1 at  $x = s$ , respectively, determines  $c_1$  and  $c_2$  so that  $G_0(x; s)$  is

$$G_0(x; s) = \frac{1}{m_0 \sinh(2m_0 x_0)} \begin{cases} \sinh(m_0(s - x_0)) \sinh(m_0(x + x_0)), & \text{if } -x_0 < x < s, \\ \sinh(m_0(x - x_0)) \sinh(m_0(s + x_0)), & \text{if } s < x < x_0. \end{cases} \quad (15)$$

Then the solution of Equation (??) is

$$\hat{p}_T(x) = \frac{1}{\sinh 2m_0 x_0} \left[ \hat{A}_1 \sinh(m_0(x_0 - x)) + \hat{A}_2 \sinh(m_0(x_0 + x)) \right] + \int_{-x_0}^{x_0} G_0(x; s) f_0(\omega, s) ds. \quad (16)$$

This is the sum of the Green's function term and a two terms that are independent solutions to the homogeneous version of Equation (??) that ensure that the inhomogeneous boundary conditions are satisfied.

## 2.2 Solution outside the slab

For the solution outside and to the left of the slab,  $x < -x_0$ ,  $\hat{p}_T(x)$  satisfies

$$\left(\frac{d^2}{dx^2} - m_1^2\right) \hat{p}_T = f_1(\omega, x), \quad (17)$$

and the boundary conditions  $\hat{p}_T(-\infty) = 0$ ,  $\hat{p}_T(-x_0) = \hat{A}_1$ . By following a Green's function method, the solution of this Sturm-Liouville system is

$$\hat{p}_T(x) = \hat{A}_1 e^{m_1(x_0+x)} + \int_{-\infty}^{-x_0} G_1(x; s) f_1(\omega, s) ds, \quad (18)$$

where  $m_1 > 0$  and the Green's function,  $G_1$ , is defined by

$$G_1(x; s) = \frac{1}{k} \begin{cases} e^{m_1(x+x_0)} \sinh(m_1(s+x_0)), & \text{if } x < s, \\ e^{m_1(s+x_0)} \sinh(m_1(x+x_0)), & \text{if } s < x < -x_0. \end{cases} \quad (19)$$

Similarly, for the solution outside and to the right of the slab,  $x > x_0$ ,  $\hat{p}_T(x)$  satisfies

$$\hat{p}_T(x) = \hat{A}_2 e^{m_2(x_0-x)} + \int_{x_0}^{\infty} G_2(x; s) f_2(\omega, s) ds, \quad (20)$$

where  $m_2 > 0$  and the Green's function,  $G_2$ , is defined by

$$G_2(x; s) = -\frac{1}{k} \begin{cases} e^{-m_2(s-x_0)} \sinh(m_2(x-x_0)), & \text{if } x_0 < x < s, \\ e^{-m_2(x-x_0)} \sinh(m_2(s-x_0)), & \text{if } s < x. \end{cases} \quad (21)$$

Putting all of this together, the (Laplace transform of) total pressure is

$$\hat{p}_T(x) = \begin{cases} \hat{A}_1 e^{m_1(x_0+x)} + \int_{-\infty}^{-x_0} G_1(x; s) f_1(\omega, s) ds, & \text{if } -\infty < x < -x_0 \\ \frac{1}{\sinh 2m_0 x_0} \left[ \hat{A}_1 \sinh(m_0(x_0 - x)) + \hat{A}_2 \sinh(m_0(x_0 + x)) \right] + \int_{-x_0}^{x_0} G_0(x; s) f_0(\omega, s) ds, & \text{if } -x_0 < x < x_0 \\ \hat{A}_2 e^{m_2(x_0-x)} + \int_{x_0}^{\infty} G_2(x; s) f_2(\omega, s) ds, & \text{if } x_0 < x < \infty \end{cases} \quad (22)$$

## 2.3 Matching solutions

For physically relevant solutions, we require that the transverse displacement (equivalently, the perturbation in transverse velocity) and the total pressure be continuous across the interfaces at  $x = \pm x_0$ .

Continuity in total pressure perturbation,  $\hat{p}_T$ , is satisfied automatically by considering the solutions inside and outside the slab given by Equations (16), (18), and (20), respectively, and our definition of  $\hat{A}_1 = \hat{p}_T(-x_0)$  and  $\hat{A}_2 = \hat{p}_T(x_0)$ .

Continuity in transverse displacement,  $\xi_x$ , can be dealt with as follows. If we make the simplification to the prescribed initial conditions such that  $\dot{\xi}_{x0} - i\omega\xi_{x0} = 0$ , then this boundary condition is equivalent to

$$\left[ \left[ \frac{1}{\rho(\omega^2 - \omega_A^2)} \frac{\partial \hat{p}_T}{\partial x} \right] \right]_{x=\pm x_0} = 0. \quad (23)$$

(Equation (8) in [1]).

Substituting the solutions given by Equations (16), (18), and (20) into these boundary conditions gives

$$\hat{A}_1(\omega) = \frac{T_1(\omega)}{D(\omega)}, \quad \hat{A}_2(\omega) = \frac{T_2(\omega)}{D(\omega)}, \quad (24)$$

where

$$T_1(\omega) = T_1[f](\omega) = -(\Lambda_2 \cosh 2m_0x_0 + \Lambda_0 \sinh 2m_0x_0)(\Lambda_1 I_0^- + \Lambda_0 I_1) - \Lambda_1(\Lambda_0 I_2 + \Lambda_2 I_0^+), \quad (25)$$

$$T_2(\omega) = T_2[f](\omega) = -\Lambda_2(\Lambda_1 I_0^- + \Lambda_0 I_1) - (\Lambda_1 \cosh 2m_0x_0 + \Lambda_0 \sinh 2m_0x_0)(\Lambda_0 I_2 + \Lambda_2 I_0^+), \quad (26)$$

$$D(\omega) = \Lambda_0(\Lambda_1 + \Lambda_2) \cosh(2m_0x_0) + (\Lambda_0^2 + \Lambda_1\Lambda_2) \sinh(2m_0x_0), \quad (27)$$

where  $\Lambda_j = \rho_j(\omega^2 - \omega_{Aj}^2)/m_j$ , for  $j = 0, 1, 2$ , and

$$I_0^\pm = I_0^\pm[f] = \int_{-x_0}^{x_0} \frac{\sinh(m_0(x_0 \pm s))}{\sinh(2m_0x_0)} f(\omega, s) ds, \quad (28)$$

$$I_1 = I_1[f] = \int_{-\infty}^{-x_0} e^{m_1(s+x_0)} f(\omega, s) ds, \quad I_2 = I_2[f] = \int_{x_0}^{\infty} e^{m_2(x_0-s)} f(\omega, s) ds, \quad (29)$$

where

$$f(\omega, x) = \begin{cases} f_1(\omega, x), & \text{if } x < -x_0, \\ f_0(\omega, x), & \text{if } -x_0 < x < x_0, \\ f_2(\omega, x), & \text{if } x_0 < x. \end{cases} \quad (30)$$

### 3 Solution in time

To recover the transverse velocity,  $v_x(x, t)$ , we employ the inverse Laplace transform (non-standard, discussed in Appendix A), such that

$$p_T(x, t) = \mathcal{L}^{-1}\{\hat{p}_T(x)\} = \frac{1}{2\pi} \lim_{L \rightarrow \infty} \int_{i\gamma-L}^{i\gamma+L} \hat{p}_T(x) e^{-i\omega t} d\omega, \quad (31)$$

where  $\gamma$  is a real number such that all the singularities of the integrand are below the contour of integration to ensure that all singularities contribute to the integral. The integral is evaluated along an infinite horizontal line in the upper half of the complex plane and is dependent on the singularities (with respect to  $\omega$ ) of  $\hat{p}_T$ , whose residues determine the value of the contour integral.

Focusing firstly on the region  $x < -x_0$ , the solution is

$$p_T(x, t) = \mathcal{L}^{-1} \left\{ \hat{A}_1 e^{m_1(x+x_0)} + \int_{-\infty}^{-x_0} G_1(x; s) f_1(\omega, s) ds \right\}, \quad (32)$$

$$= \mathcal{L}^{-1} \left\{ \hat{A}_1 e^{m_1(x+x_0)} \right\} + \mathcal{L}^{-1} \left\{ \int_{-\infty}^{-x_0} G_1(x; s) f_1(\omega, s) ds \right\}. \quad (33)$$

#### 3.1 Asymptotic solution for large time

To study the asymptotic behaviours of the total pressure perturbation, we start with the asymptotic behaviours of  $A_1(t) = p_T(-x_0, t)$  and  $A_2(t) = p_T(x_0, t)$ . These variables can be determined, using the inverse Laplace transform (non-standard, discussed in Appendix A), to be

$$A_1(t) = \frac{1}{2\pi} \lim_{L \rightarrow \infty} \int_{i\gamma-L}^{i\gamma+L} \frac{T_1(\omega)}{D(\omega)} e^{-i\omega t} d\omega, \quad A_2(t) = \frac{1}{2\pi} \lim_{L \rightarrow \infty} \int_{i\gamma-L}^{i\gamma+L} \frac{T_2(\omega)}{D(\omega)} e^{-i\omega t} d\omega, \quad (34)$$

where  $\gamma$  is a real number such that all the singularities of the integrands are below the contour of integration. The integrals are evaluated along an infinite horizontal line in the upper half of the complex plane.

Since the problem of finding the solution is now reduced to solving a complex integral, it is dependent on the singularities (with respect to  $\omega$ ) of  $T_1$ ,  $T_2$ , and  $D$  (so that we can construct a Bromwich contour such that it is confined to a single-valued branch) and the zeros of  $D$  (whose residues determine the value of the contour integral).

To determine the singularities of these functions, we determine the singularities of the constituent functions, as follows.

- The functions  $\Lambda_j^2$  are rational functions of  $\omega$  with simple poles at  $\omega = \pm\omega_{0j}$ , for  $j = 0, 1, 2$ .
- $\Lambda_j$ , for  $j = 0, 1, 2$ , involve radicals and have (algebraic) branch points at  $\omega = \pm\omega_{Aj}$ ,  $\pm\omega_{0j}$ , and  $\pm\omega_{Tj}$ , respectively.<sup>1</sup>
- The functions  $\cosh(z)$  and  $\sinh(z)$  are entire functions of  $z$  with only even and odd terms in their respective series expansions. Therefore,  $\cosh(z)$  and  $z \sinh(z)$  are entire functions of  $z^2$ . Hence,  $\cosh(2m_0x_0)$  and  $\Lambda_0 \sinh 2m_0x_0$  have only simple poles at  $\omega = \omega_{T0}$ .
- The integrands of  $I_0^\pm$  are integrated with respect to  $s$ . Therefore, the singularities of  $I_{1,2}$  are precisely the singularities of the integrands. The function  $g(z) = \sinh(az)/\sinh(bz)$ , for constants  $a$  and  $b \neq 0$  are entire functions of  $z$ , containing only even powers (once  $g$  has been redefined as to remove the removable singularity at  $z = 0$ ). Therefore, for another complex function  $h$ , the singularities of the composition  $g \cdot h$  are precisely the singularities of the function  $h(z^2)$ . Hence, by letting  $h(\omega) = m_0$ ,  $a = s \pm x_0$ , and  $b = 2x_0$ , it follows that  $\sinh(m_0(s - x_0))/\sinh(2m_0x_0)$  has simple poles at  $\omega = \pm\omega_{T0}$ .
- To determine the singularities of  $I_{1,2}$ , we need consider the singularities of the integrands. The functions  $e^{a\sqrt{z}}$  and  $e^{\frac{a}{\sqrt{z}}}$ , for constant  $a \neq 0$  have branch points at  $z = 0$  that are algebraic (of ramification index 2) and transcendental, respectively. Therefore, by setting  $a = x_0 \pm s$ , it follows that the functions  $e^{m_j(x_0 \pm s)}$ , and therefore  $I_j$ , have algebraic branch points at  $\omega = \pm\omega_{Aj}$  and  $\pm\omega_{0j}$  and transcendental branch points at  $\pm\omega_{Tj}$ .

---

<sup>1</sup>More precisely,  $\omega = \pm\omega_{Aj}$ ,  $\pm\omega_{0j}$ , and  $\pm\omega_{Tj}$  are the ramification points corresponding to the branch points  $\Lambda_j(\omega)$ , each with ramification index 2. However, the language used in the main text is common shorthand that is considered synonymous.

By the algebra of branch points, the set of branch points of a sum of functions is the union of the branch points of the constituent functions. Therefore, the branch points of both  $T_1$  and  $T_2$  are  $\omega = \pm\omega_{A0,1,2}$  (algebraic),  $\pm\omega_{00,1,2}$  (algebraic),  $\pm\omega_{T0}$  (algebraic), and  $\pm\omega_{T1,2}$  (transcendental). The dispersion function  $D$  has branch points at  $\omega = \pm\omega_{A0,1,2}$ ,  $\pm\omega_{00,1,2}$ , and  $\pm\omega_{T0,1,2}$ , all of which are algebraic.

TO DO: Redo the above to show that we have algebraic branch points at all of the  $\omega_{A,0,T}$  corresponding to the Alfven, slow and fast continua, corresponding to leaky modes. So we have 18 branch points. How should be choose the branch cuts? We need to ensure we are confined to a single Riemann sheet i.e. single valued. See e.g. Fig 6 in Sedlacek 1970.

*The above analysis determines that the singularities of each function  $T_1(\omega)$ ,  $T_2(\omega)$ , and  $D(\omega)$  are precisely the algebraic branch points at  $\omega = \pm kv_{A1}$  and  $\omega = \pm kv_{A2}$ .*

## 3.2 Asymptotic solution - non-magnetic external plasma

If the external plasma is non-magnetic, *i.e.*  $v_{A1} = v_{A2} = 0$ , then the integral has (algebraic) branch points at  $\omega = \pm\omega_{A0}$ ,  $\pm\omega_{00,1,2}$ , and  $\pm\omega_{T0}$ . The contour for the inverse Laplace transform can be modified as shown in Figure 1. To ensure that the contour remains on a single Riemann surface, it is modified around the branch cuts so as to encircle the poles.

### 3.2.1 Poles (AKA eigenfrequencies)

Let  $v_A > c_i$  for  $i = 0, 1, 2$ , then there can exist, in general:

1. 2 slow surface modes,
2. an infinite number of slow body modes,
3. 2 fast surface modes.

1 and 2 exist for all values of  $kx_0$ . 3 exist only for  $kx_0$  values greater than a cutoff value. Analytical expressions for the behaviour of the eigenmodes do not exist in general. It is at this point that we are forced to make two simplifications to the model:

- The thin-slab approximation, so that  $kx_0 \ll 1$

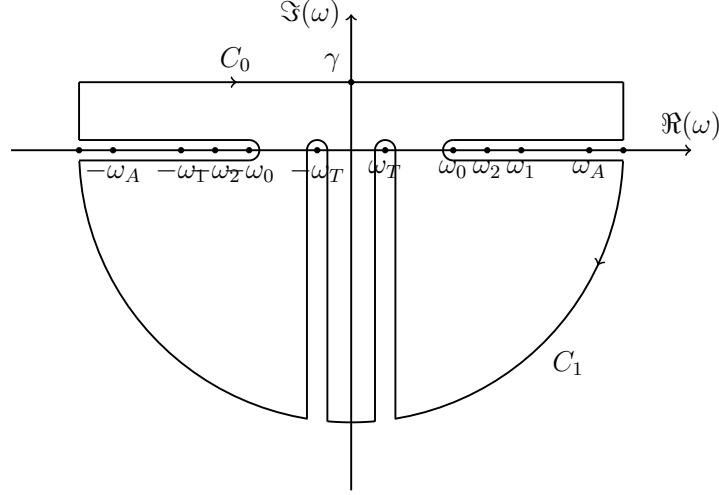

Figure 1: Bromwich contour for the complex integration of  $\tilde{A}_{1,2}$ .

- The approximate symmetry simplification, so that  $\rho_1 \approx \rho_2$ .

The eigenmodes of an asymmetric magnetic slab under these simplifications are given by the following expressions:

- Slow quasi-sausage surface modes:

$$\omega^2 = k^2 c_T^2 \left[ 1 - \frac{2(kx_0)(c_0^2 - c_T^2)}{(c_0^2 + v_A^2) \left( \frac{\rho_0}{\rho_1} \frac{(c_1^2 - c_T^2)^{1/2}}{c_1} + \frac{\rho_0}{\rho_2} \frac{(c_2^2 - c_T^2)^{1/2}}{c_2} \right)} \right], \quad (35)$$

which is less than  $k^2 c_T^2$  and exists only when  $c_1 > c_T$  and  $c_2 > c_T$ .

- If  $c_1 = c_2 = c_e$  (and therefore  $\rho_1 = \rho_2 = \rho_e$ ), then there exists a fast sausage surface mode:

$$\omega^2 = k^2 c_e^2 \left( 1 - \left[ \frac{\rho_e}{\rho_0} \frac{c_e^2 (c_0^2 - c_e^2) (kx_0)}{(c_0^2 + v_A^2) (c_T^2 - c_e^2)} \right]^2 \right) \quad (36)$$

in the thin slab limit.

- Slow quasi-kink surface mode:

$$\omega^2 = \frac{k^2 x_0 v_A^2 \left( \frac{\rho_0}{\rho_1} m_1 + \frac{\rho_0}{\rho_2} m_2 \right)}{\left( \frac{\rho_0}{\rho_1} m_1 x_0 + \frac{\rho_0}{\rho_2} m_2 x_0 \right) + 2} \approx \frac{1}{2} k^2 v_A^2 \left( \frac{\rho_0}{\rho_1} + \frac{\rho_0}{\rho_2} \right) kx_0. \quad (37)$$

- Quasi-sausage body solutions:

$$\omega^2 = k^2 c_T^2 \left( 1 + \frac{c_T^4 (kx_0)^2}{c_0^2 v_A^2 \pi^2 j^2} \right), \quad j = 1, 2, \dots \quad (38)$$

- Quasi-kink body solutions:

$$\omega^2 = k^2 c_T^2 \left( 1 + \frac{c_T^4 (kx_0)^2}{c_0^2 v_A^2 \pi^2 (j - \frac{1}{2})^2} \right), \quad j = 1, 2, \dots \quad (39)$$

Solution of the inverse Laplace transform is the sum of the residues at these points.

As shown by [2], under the approximate symmetry simplification, the dispersion function,  $D(\omega)$ , becomes

$$D(\omega) = \frac{1}{2\Lambda_1 \Lambda_2} D_k(\omega) D_s(\omega), \quad (40)$$

where

$$D_k(\omega) = \Lambda_0(\Lambda_1 + \Lambda_2) + 2\Lambda_1 \Lambda_2 \coth(m_0 x_0), \quad (41)$$

$$D_s(\omega) = \Lambda_0(\Lambda_1 + \Lambda_2) + 2\Lambda_1 \Lambda_2 \tanh(m_0 x_0). \quad (42)$$

This can be further simplified for surface modes under the thin-slab approximation, to first order in  $kx_0$ , to

$$D_k(\omega) = \Lambda_0(\Lambda_1 + \Lambda_2) + 2\Lambda_1 \Lambda_2 \frac{1}{m_0 x_0}, \quad (43)$$

$$D_s(\omega) = \Lambda_0(\Lambda_1 + \Lambda_2) + 2\Lambda_1 \Lambda_2 m_0 x_0. \quad (44)$$

### 3.2.2 Residues

In order to calculate the residue of each pole, we must determine their order. Firstly, we will demonstrate the calculation for the slow kink surface mode,  $\omega = \omega_{sks}$ , and leave the rest, which are similar, to the reader. Clearly,  $D_s(\omega_{sks}) \neq 0$ , and with some algebra,

$$D_k(\omega) = -\frac{\rho_1 \rho_2 k R}{m_0 m_1 m_2} (\omega^2 - \omega_{sks}^2), \quad (45)$$

so each of  $\omega = \pm\omega_{sks}$  are simple zeros of  $D_k$  and hence of  $D$ , therefore, they are simple poles of the integrand in question.

Therefore, the residue of the integrand at  $\omega = \omega_{sks}$  is

$$\text{Res} \left\{ \frac{T_1}{D} e^{i\omega t}; \omega = \omega_{sks} \right\} = \lim_{\omega \rightarrow \omega_{sks}} \left\{ (\omega - \omega_{sks}) \frac{T_1(\omega)}{D(\omega)} e^{i\omega t} \right\} \quad (46)$$

$$= -\frac{2m_0m_1m_2\Lambda_1\Lambda_2}{\rho_1\rho_2kR} \Big|_{\omega=\omega_{sks}} \frac{T_1(\omega_{sks})}{2\omega_{sks}D_s(\omega_{sks})} e^{i\omega_{sks}t} \quad (47)$$

$$= \frac{\omega_{sks}m_0}{kR} \frac{T_1(\omega_{sks})}{D_s(\omega_{sks})} e^{i\omega_{sks}t}. \quad (48)$$

Similarly, the residue at  $\omega = -\omega_{sks}$  is

$$\text{Res} \left\{ \frac{T_1}{D} e^{i\omega t}; \omega = -\omega_{sks} \right\} = -\frac{\omega_{sks}m_0}{kR} \frac{T_1(\omega_{sks})}{D_s(\omega_{sks})} e^{-i\omega_{sks}t} \quad (49)$$

since  $T_1$  and  $D_s$  are even functions of  $\omega$ .

## A Non-standard Laplace transform

Consider a function  $f(t)$ , whose standard Laplace transform,  $F_1(\omega)$ , and non-standard Laplace transform,  $F_2(\omega)$ , are

$$F_1(\omega) = \int_0^\infty f(t) e^{-\omega t} dt, \quad \text{and} \quad F_2(\omega) = \int_0^\infty f(t) e^{i\omega t} dt. \quad (50)$$

Trivially,  $F_1(-i\omega) = F_2(\omega)$ . Using the standard inverse Laplace transform, and letting  $\gamma$  be real and greater than the real part of all the singularities of  $F_1(\omega)$ , the original function  $f(t)$  can be written

$$f(t) = \frac{1}{2\pi i} \lim_{T \rightarrow \infty} \int_{\gamma-iT}^{\gamma+iT} F_1(\omega) e^{\omega t} d\omega, \quad (51)$$

$$= \frac{1}{2\pi i} \lim_{T \rightarrow \infty} \int_{i\gamma-T}^{i\gamma+T} F_1(-i\omega) e^{-i\omega t} (-i d\omega), \quad (52)$$

$$= \frac{1}{2\pi} \lim_{T \rightarrow \infty} \int_{i\gamma-T}^{i\gamma+T} F_2(\omega) e^{-i\omega t} d\omega. \quad (53)$$

Therefore, the inverse transform of the non-standard Laplace transform is

$$f(t) = \frac{1}{2\pi} \lim_{T \rightarrow \infty} \int_{i\gamma-T}^{i\gamma+T} F_2(\omega) e^{-i\omega t} d\omega. \quad (54)$$

## B Approximately symmetric slab parameter expansions

For an approximately symmetric slab, that is, when  $\rho_2 = \rho_1(1 + \epsilon)$  where  $\epsilon \ll 1$ , then the first order expansions in  $\epsilon$  of other relevant parameters are given below.

- $c_2^2 = c_1^2 \frac{\rho_1}{\rho_2} = c_1^2 \left( \frac{1}{1+\epsilon} \right) \approx c_1^2 (1 - \epsilon)$ .
- $m_2 = \sqrt{k^2 - \frac{\omega^2}{c_2^2}} = \sqrt{k^2 - \frac{\omega^2}{c_1^2} (1 + \epsilon)} \approx m_1 \left( 1 - \frac{\omega^2}{2c_1^2 m_1^2} \epsilon \right)$ .
- $\Lambda_2 = \frac{\rho_2 \omega^2}{m_2} = \frac{\rho_1 (1+\epsilon) \omega^2}{m_1 \left( 1 - \frac{1}{2m_1^2} \epsilon \right)} \approx \frac{\rho_1 (1+\epsilon) \omega^2}{m_1} \left( 1 + \frac{1}{2m_1^2} \epsilon \right) = \Lambda_1 \left( 1 + \epsilon \left[ 1 + \frac{\omega^2}{2c_1^2 m_1^2} \right] \right)$ .
- $I_2 = \int_{x_0}^{\infty} e^{m_2(x_0-s)} f(\omega, s) ds = \int_{-\infty}^{-x_0} e^{m_2(x_0+s)} f(\omega, s) ds$ , if  $f(\omega, -x) = f(\omega, x) \forall x \in (-\infty, -x_0)$ . Therefore,

$$I_2 = \int_{-\infty}^{-x_0} e^{\epsilon m_1 M(x_0+s)} e^{m_1(x_0+s)} f(\omega, s) ds, \text{ where } M = -\frac{\omega^2}{2c_1^2 m_1^2}, \quad (55)$$

$$= I_1 + \epsilon m_1 M \int_{-\infty}^{-x_0} (x_0 + s) e^{m_1(x_0+s)} f(\omega, s) ds. \quad (56)$$

It doesn't seem that this simplifies into  $I_1(1 + J\epsilon)$  without making  $f$  less general.
